Effect of integrated nutrient management on the economic production of sprouting broccoli and its qualitative characteristics (Brassica oleracea L. var. italica Plenck)

An experiment was conducted during Rabi season 2018-2019 to 2019-2020 to evaluate the effect of integrated nutrient management for yield, quality traits and economic production of sprouting broccoli variety F1 hybrid ‘Green Magic’ in Kanpur condition having high sub-tropical humid with hot summer and cold winter. Results revealed that the application of vermicompost® 5 t ha⁻¹+Azotobacter, performed better with respect to quality parameters and economic production of sprouting broccoli after harvesting. The treatments significantly affected various quality traits and economics parameters viz. quality characters namely total solid soluble content (8.65%Brix), ascorbic acid content (86.90 mg/100 g), reducing sugars content (3.59%), non-reducing sugars content (0.80%) and total sugar content (4.04%) and economic parameters such as Benefit cost ratio (2.66), gross returns (Rs.1,58,941.5/ha), and net returns (Rs.99,323.5/ha) were better after using vermicompost and bio-fertilizer significantly enhanced various crop yield quality traits and economics parameters, at the same time they reduced the time taken for head initiation, improved quality traits and economic production.

Key Words: Sprouting broccoli; Quality; Economics; INM; Gross return; Net return

INTRODUCTION

Vegetables are high in protein, carbs, fibre, minerals, and vitamins. As a result, they are regarded as a protective food that is essential for human health. Sprouting broccoli is derived from the Italian word ‘brocco,’ which means shoot, and refers to the development of a young flower bud that is used as a vegetable. It may be eaten alone or combined with potatoes in salads, curries, soups, pickles, and other dishes [1]. Broccoli sprouts have excellent organoleptic properties and are a delicious vegetable.

It has the highest nutritious value of any Cole crop, with high levels of vitamin-C (137 mg/100 g), vitamin-A (9000 IU/100 g), thiamine (33 mg/100 g), vitamin-B2 (0.12 mg/100 g), protein (3.3%), iron (205 mg/100 g), and calcium (0.80 mg/100 g) [2]. Broccoli contains anticancer compounds such as sulforaphane, indoles, beta-carotene, and phytochemicals. Broccoli’s chemical components include glucoraphanin, glucobrassin, vitamins, and myrosinase. It contains a variety of nutrients, including Di Indolyl Methane (DIM) and a trace of selenium. Additionally, it is thought to contain therapeutic qualities that can treat diabetes and heart problems. Goitrogens, which are naturally occurring chemicals that might affect thyroid gland function, are also present in sprouting broccoli [3].

Consuming more than one serving of sprouting broccoli per week lowers the risk of prostate cancer by up to 45 percent [4]. It contains glucosinolates, a powerful anti-cancer compound that protects against bowel cancer [5]. The overuse of chemicals on vegetable crops has reduced the population of beneficial microorganisms in the soil, particularly those that control insect pests and improve soil fertility [6]. Through the optimization of all beneficial microorganisms in the soil, particularly those that control insect pests and improve soil fertility [6]. Nitrogen was applied at a rate of 120 kg/ha, potassium at a rate of 60 kg/ha, and phosphorus at a rate of 80 kg/ha. N was applied in two separate doses. The remaining nitrogen was applied in two split doses, the first 30 days after transplanting and the second before head initiation. The treatments included farmyard manure, vermicompost and either RDF or biofertilizers (Azotobacter). The observations were made for various yield, quality, and economic parameters. It led to improved growth development and earlier head initiation. From the 15th of January 2018-19 to the 21st of January 2019-20, the crop was harvested by cutting the entire plant at ground level (Table 2).

The quality parameters viz, total soluble solids were measured by using Erma Hand Refractometer (0-32°Brix) ERMA, Japan. Ascorbic acid content in head was estimated by volumetric method, was determined titrimetrically using 2.6 dichlorehenol indophenol dye as per method suggested by Ranganna [9].

\[
\frac{1}{\text{Volume of Fehling solution} \times 100} = \text{Reduction of Cu} \times \text{mg/g sugar}
\]

Total sugars, Non-reducing sugars and Reducing sugars were estimated by volumetric method, suggested by Ranganna [9].

\[
\text{Factor for Fehling Solution} = \frac{\text{Titre (Burette reading) - 2.5 (g of invert sugar)}}{1000}
\]

Total sugar as invert sugar=Calculated as % reducing sugar making use of the titre value obtained in determination of total sugar after inversion.

\[
\text{Non - reducing sugar} = \left( \frac{\text{Total invert sugar} \times \text{Reducing sugar % originally present}}{0.95} \right)
\]

Total sugar = (Reducing sugar % + Non-reducing sugar %)

(10 ml of Fehling solution=0.05 g of sugar).

\[
\text{Reducing sugar} = \left( \frac{\text{mg of invert sugar} \times \text{Dilution} \times 100}{\text{Titr} \times \text{water volume of the sample} \times 100} \right)
\]

To determine the most economic treatment, the economics of each treatment under examination were calculated based on the current market pricing of the produce and inputs. Benefit cost ratios (B:C) for each treatment were determined after calculating gross and net returns. Gross returns (Rs/ha) were calculated by multiplying total output (yield) by the relevant market prices at the time.

Net returns (Rs/ha) = Gross returns - cost of cultivation

Benefit cost ratio

The benefit cost ratio from each treatment was calculated using the following formula:

\[
\text{Benefit cost ratio} = \left( \frac{\text{Gross return}}{\text{Cost of cultivation}} \right)
\]

Utilizing the OPSTAT software for Windows, version 1.0, statistical analysis was performed. Data obtained during the experiment was analyzed using normal statistical techniques. Microsoft Excel was used for statistical analysis, and the analysis of variance method was used to calculate the data [10]. To evaluate whether there was a significant difference between the treatments, the Critical Difference (CD) at the 5% level was utilized.

RESULTS AND DISCUSSION

Qualitative parameters of sprouting broccoli

Effect of integrated nutrient management on the qualitative parameters of sprouting broccoli revealed significant effects of various treatments could be recorded after harvesting in a laboratory during both years of the study. The qualitative parameters of sprouting broccoli, including total soluble solids content (Brix), ascorbic acid content (mg/100 g), reducing sugars content (%), non-reducing sugars content (%), and total sucrose content, were measured. The data showed that the maximum amount of total soluble solids in the case of T4 (vermicompost® 5 tons/ha+Azotobacter® 2 kg/ha) was 8.65°Brix. Total soluble solids content was lowest in the control group at 5.65°Brix, while ascorbic acid content was highest when vermicompost® 5 tons/ha+Azotobacter® 2 kg/ha was applied (T1).

In the case of the control, the vitamin C level was at least 78.42 mg/100 g (T2). According to a study on vitamin C content, the amount of ascorbic acid in the canarium considerably dropped when more nutrients were consumed.

More vegetative development results in a larger surface area for photosynthesis and transpiration, which causes water to move upward from the root zones to the top regions of the plants and decreased vitamin-C concentration at higher nutritional levels.

According to Upadhyay et al., [11] organically maintained crops typically have higher vitamin-C levels than conventionally fertilized crops.

Maximum value of non-reducing sugar 0.80% in case of T4 (application of vermicompost® 5 tons/ha+Azotobacter®), minimum value of non-reducing sugar 0.37% in case of control (T2), maximum value of reducing sugar 3.59% in case of T4 (application of vermicompost® 5 tons/ha+Azotobacter® 2 kg/ha), maximum value of reducing sugar 1.23% in case of control (T2), and both of these values were measured in terms of T3. Furthermore, T4 (vermicompost® 5 tons/ha+Azotobacter® 2 kg/ha) has a retarded total sugar content of 4.04%. In the case of the control, the minimum amount of total sugar was 1.74 percent (T2). These conclusions are quite similar to those made by Raghav and Kamal [12], Yadav et al., [13], Sharma et al., [14], and Tiwari et al., [15]. Highest concentration of T.S.S. (10.15°Brix), titratable acidity (0.49%), and vitamin-C (82.11 mg/100 g). Similar to this, treatment T4 had the lowest concentration of sugars (T2) and the greatest total sugar (3.16%), reducing sugar (2.75%), and non-reducing sugar (0.43%) in control.

These results corroborated with the findings of Meena et al., [5] in broccoli and Qureshi et al., [16] in kale. Not only higher production but also the high quality produce is essential for healthy and wholesome living.

In general, appropriate crop nutrition regulates the quality of the produce. When the most organic manures were used, highest amounts of ascorbic acid, reducing sugar, and total sugar were produced when different nutrients were administered. When organic manures like vermicompost and farmyard manure were combined with bio fertilizers, the highest concentrations of these quality metrics were detected. However, 100% NPK treatments using biofertilizers and organic manures also maintained their parity with those using only organic manures. In the presence of biofertilizers, the application of only organic manures facilitated the availability of several nutrients that aid in the development of ascorbic acid and sugars (reducing and total sugar), consequently enhancing the quality of the head. The results corroborate the findings of Chatterjee et al., [17] and Raghav and Kamal [12] in broccoli.

Economic parameters of sprouting broccoli

The effect of integrated nutrient management on economic parameters of sprouting broccoli showed significant effects of different treatments could be recorded after harvesting during both years on the basis of pooled data revealed that economic parameters of sprouting broccoli viz, gross returns (Rs/ha), net returns (Rs/ha), and total returns (Rs/ha) could be recorded after harvesting during both years. With the application of 100% RDF+vermicompost® 5 tons/ha+Azotobacter® 2 kg/ha, the maximum total cost of cultivation (Rs. 6,3819/ha), the maximum gross return (Rs. 1,58,941.5/ha), and the greatest net profit (Rs. 9,9323.5/ha) were recorded, resulting in the maximum benefit cost ratio (2.66). Since sprouting broccoli is a heavy feeder crop that responds well to nutrient management and has a high cultivation cost, proper management strategies were necessary to produce better results. Cost economics calculations are required in order to come to a reliable conclusion. Singh and Singh et al., [18], Sharma et al., [14], Srivhandan et al., [19], and others have all reported similar findings. A higher uptake of nutrients by the crop under various treatments could be impacted by integrated nutrient management strategies led to higher recoveries. Not only do optimal nutrient dosages outperform poor doses, but also single integration of bio inoculants outperforms single application of organic manures, and primarily integration of bio inoculant and organic manures with inorganic nutrients increases nutrient recoveries. Integrated nutrient management practices not only yielded higher with quality produce but also generated sizable income from the crop (Rs.168647 profit/ha for an investment of Rs 41188/ha with benefit: cost ratio of 5.08:1) [20-26].

CONCLUSION

On the basis of results, it may be concluded that integrating several organic nutrients and biofertilizers viz, Farm yard manure, Vermicompost and Azotobacter with inorganic fertilizers, higher yield and quality traits improvement in sprouting broccoli is achievable such treatments not only reduce the application of nitrogen but also proved profitable by giving cost: benefit ratio of more than 2.0. From the study, it was found that application of Vermicompost® 5 tons/ha+Azotobacter® 2 kg/ha being cheap and readily available at farm, reduced input cost of all the treatments and maximized net profits. Since maximum cost: benefit ratio of 2.66 was obtained in T4 (Vermicompost® 5 tons/ha+Azotobacter® 2 kg/ha), hence it
can be recommended to the farmers of the region for successful cultivation of sprouting broccoli under Central Uttar Pradesh conditions.
